

HealthConnect Clinic, Week 8

Final Integration Readiness (Data Analytics Track)

Prepared by: Hillary Emmanuel | Programme: AnalystLab Africa

What is my final component?	The HealthConnect Final Analytics & Decision Support Package: a validated Power BI dashboard (five KPIs with confidence-interval error bars, tested slicers), the corrected double-risk segment definition, and the business insights and recommendations built on them.
What problem does it address?	Identifying which patients are most likely to miss their appointment, and by how much, so reminder and intervention effort can be targeted rather than spread evenly across all bookings.
What is its current status?	Tested and validated as of Week 7 (all five KPIs reproduced independently, findings retested against new segments), and packaged for Week 8 into the executive summary, final report, presentation slides, and the HC-POD integration record.
What did I improve during Week 7?	Corrected the double-risk segment threshold from ≥ 46 to ≥ 31 days after root-causing a reproduction failure; independently reproduced all five KPIs from the raw dataset; confirmed the 15+km distance effect is real and not redundant with lead time; added and tested dashboard slicers; closed the KPI 5 (cancellation-to-no-show ratio) testing gap.
Which other track(s) does it depend on?	The DS track collaborator, for merging the corrected ≥ 31 double-risk threshold into their train_improved.py feature so code and DA figures agree. No other cross-track dependency.
Which track(s) depend on my output?	The DS track collaborator (uses the validated double-risk segment and lead-time finding as model input and business rationale).
What output will I provide?	Final dashboard and report, final KPIs, validated findings, key visualisations, business insights, recommendations, analytical limitations, the cross-track contribution record, an executive summary, and presentation slides.
What output do I need from another track?	Confirmation from the DS track collaborator that the corrected ≥ 31 threshold has been merged into train_improved.py, so the cross-track record can close cleanly. No other input is required from another track for this component.
What evidence demonstrates readiness?	The Week 7 Analytics Testing & Refinement Report, the Week7 Testing & Validation Record, the cross-track evidence files (segment retest CSVs and output logs under both model types), and the dashboard slicer test results against the documented expected values.
What limitations remain?	DS collaborator's flag correction not yet merged. reminder_sent and reminder_channel effects are less thoroughly tested than lead time and distance. Findings are validated on one 5,000-row fictional dataset only, with no held-out or external data. The double-risk call pilot is a design, not a run.
